DOI: <https://doi.org/10.1590/2177-6709.22.0.00-000.oar>

It is possible to unify 3-dimensional customized orthodontic techniques and 3-dimensional surgical technology. In this case report, it is introduced a treatment scheme consisting of passive self-ligation customized brackets and virtual surgical planning combined with the orthognathic surgery-first approach in a Class III malocclusion patient. Excellent facial and occlusal outcomes were obtained in a reduced treatment time of 5 months.

INTRODUCTION

Accurate surgical treatment starts with precise diagnosis by evaluating all dimensions and determining the nature of deformity because it might be a combination of hard and soft tissue components.¹

The main limitation of conventional surgical planning is its 2-dimensional approach that involves clinical examination, extraoral and intraoral photographs, lateral and posteroanterior cephalograms, and plaster dental models.^{2,3} To overcome those deficiencies, cone-beam computed tomography (CBCT) for imaging the craniofacial region heralds a true paradigm shift from a 2-dimensional to a 3-dimensional (3D) approach.⁴

Computer aided surgical simulation (CASS) utilizing 3-dimensional images obtained from multi-slice computer tomography (MSCT)/cone beam computer tomography (CBCT) has been successfully performed previously to plan craniofacial surgery.⁵⁻⁸ Also, CASS has been combined with the surgery-first approach (SFA) to demonstrate two useful and practical methods for planning these cases.⁹

Furthermore, the patient can be virtually visualized by generating a fusion model with digital dental casts, a CBCT reconstructed bony volume and textured facial soft tissue image.^{10,11} Additionally, with this fusion model the clinicians can accurately create surgical splints using the computer-aided design/computer-aided manufacturing (CAD/CAM) system for successful surgical treatments.^{11,12}

Recently, significant technological advancements have been made in computer-aided orthodontic treatment. In the Insignia system (Ormco Corporation, Orange County, CA), PVS impressions are digitized with computed tomography to produce highly detailed digital models or an intraoral dental scanner (Lythos, Ormco Corporation, Orange County, CA) is used to generate 3D digital models. The orthodontist adjusts the digital setup using a real-time 3D interface, while referring to the patient's intra and extraoral photographs and radiographs for consideration of esthetic treatment goals. After the clinician approves the final setup, the customized brackets, tubes, and arch-wires are fabricated and bracket-positioning jigs are provided for accurate indirect transfer.¹³

In this case report, 3D virtual customized bracket design (Insignia, Ormco Corporation, Orange County, CA) is integrated with 3D virtual surgical planning along with fabrication of digital surgical splints using a CAD/CAM technique. This article aims to report how the use of 3D digital technology, self-ligation and the SFA can drastically reduce the treatment time.

CASE REPORT

A 21-year-old Hispanic male reported to the orthodontist office with the primary complaint of not feeling comfortable with the bite and chin projection (Fig 1). A subsequent clinical examination showed that the profile had worsened since a previous orthodontic treatment.

Systemically, he referred controlled Diabetes Mellitus Type I. The extraoral examination showed concave facial profile, with a slight maxillary hypoplasia, significant chin projection, upper lip protrusion and adequate nasolabial angle (Fig 1). Dentally, the patient presented a Class III malocclusion with proclined upper incisors and retroclined lower incisors, edge to edge bite, lower proper alignment and spacing of 2mm in the upper arch (Fig 1; Fig 2, Fig 3A). The panoramic x-ray showed mild different ramus lengths. (Fig 3B). Skeletally, h Class III pattern with mandibular prognathism and macrognathism were observed (Fig 3A, 3C).

The treatment objectives were to correct the Class III skeletal pattern, to improve profile, to increase overjet and to improve facial aesthetics. The treatment options presented were presurgical orthodontic treatment followed by mandibular setback and SFA, or mandibular setback followed by fixed appliances to align, level and stabilize the occlusion. Considering that the patient's chief concern was his facial esthetics, it was decided to proceed with SFA, because the patient wanted immediate facial change. This approach would avoid deterioration in his profile and malocclusion during presurgical orthodontics and would also take advantage of the biological potential of the RAP.

A Computed Tomography (TC) (Bright Speed Elite, General Electric, and Fairfield, Connecticut, USA) was taken for the construction of a model of the skull⁸ with PROPLAN CMF (Materialise,

Plymouth, MIs). The surgical plan was mandibular setback (Fig 4). The virtual design was transferred to the CAD/CAM software for production of surgical splints. The intermediate and final splints, were physically generated by a 3D printer (Fortus 250mc, Stratasys, Eden Prairie, MN, USA) with hybrid epoxy-acrylate polymer.

The first step in the Insignia system (Ormco Corporation, Orange, CA) for custom-designed orthodontics is to send precise polyvinyl siloxane impressions as well as photographic and radiographic information to the manufacturer. The brackets chosen were Insignia self-ligating (SL) brackets, which are the customized version of Damon Q SL brackets (Ormco Corporation, Orange, CA).¹⁴ The final setup for the patient was approved with an overcorrection of lower incisors torque, ensuring optimal expression of the lower incisors decompensation exploiting the massive RAP after orthognathic surgery.

(Fig 5) The wire sequence selected was Cooper NiTi 0,014 inch, Cooper NiTi 0,014 x 0,025 inch, Cooper NiTi 0,018x0,025 inch, TMA 0,019x0,025 inch and stainless steel 0,019x0,025 inch (Ormco Corporation, Orange, CA). The brackets were bonded 3 days before surgery and no archwire was placed.

In the day of the surgery, immediately before intubation assisted by a fiber optic probe, Copper Ni-Ti 0.014 inch (Ormco Corporation, Orange, CA) archwires were placed (Fig 6). After mandibular setback surgery by sagittal osteotomy, under brain activity monitoring and once a suitable rigid fixation and postoperative occlusion were established, ¼ 3.5 oz intermaxillary elastics were applied with Class III vector.

After 15 days 1/8 3.5 oz intermaxillary elastics were used (Fig 7) and the archwires were changed to 0,014x0,025 Cooper Ni-Ti (Ormco Corporation, Orange, CA). One month after surgery .018x.025

DISCUSSION

SFA was first proposed by Nagasaka and colleagues in 2009¹⁵ With the orthognathic surgery performed before the orthodontic correction, total treatment time could be reduced to even less than the average period for presurgical orthodontics.¹⁶⁻¹⁹ Considering the number of patients who want orthognathic surgery mainly for esthetic reasons and would appreciate a shorter treatment time, SFA offers an attractive alternative for managing skeletal malocclusions while improving patients' self-esteem and function at the beginning of treatment.^{20,21}

The authors described several advantages offered by the surgery-first approach: (1) Improvement in patient's facial esthetics and dental function in early treatment, rather than following a possible period of years, (2) improvement in patient's swallowing and speech functions after surgery, (3) the proceeding of orthodontic tooth movement at a much faster pace following surgery, thus reducing the overall treatment time, (4) improved cooperation of the patient during orthodontic treatment, (5) easier orthodontic tooth movement following restoration of the normal functional and anatomic relationships of the bony skeleton

861 and surrounding soft tissues and (6) stability of results
862 equal to, or in some cases superior to, those achieved
863 using the traditional orthodontics-first approach.²²

864 Most articles recommended that orthodontic ap-
865 pliances should be fitted prior to surgery, even when
866 using a surgery-first approach. Studies reported bond-
867 ing the orthodontic brackets immediately before,^{15,23}
868 1 week before,²⁴⁻²⁶ 1 month before²⁷⁻²⁹ or 1-2 months
869 before³⁰ surgery. Only one of the papers reported the
870 total elimination of preoperative orthodontic treat-
871 ment and the fitting of orthodontic brackets 10-14
872 days after surgery²⁰ Studies described that active
873 orthodontic force can be applied before²⁶⁻²⁹ or shortly
874 after^{15,23-25,30} surgery. Preoperative orthodontic prep-
875 aration can, therefore, be started immediately before
876 or approximately 1-2 months before surgery. Occa-
877 sionally, it might be completely eliminated.

879 The shortest reported treatment time for postop-
880 erative orthodontic treatment was 4 months for cor-
881 rection of a skeletal Class III malocclusion with ante-
882 rior open bite and dental crowding²⁶ and 4.5 months
883 in the management of unilateral condylar hyperplasia,¹¹
884 similar to this case report with total treatment
885 time of 5 months. Most studies described completing
886 postoperative orthodontic treatment within approxi-
887 mately 1 year^{15,27,28,30} or in 6-9 months.^{20,23,25} Treat-
888 ment time was approximately 6-12 months shorter
889 using a SFA, compared to using a conventional or-
890 thodontics-first approach. Only one study described
891 similar treatment time (approximately 1.5 years) for
892 both approaches.²⁹

893 There is no doubt that SFA requires precise and
894 accurate diagnosis and planning. Post-surgical ortho-
895 dontic movements must be carefully executed ac-
896 cording to the surgical plan, which implies constant
897 communication between orthodontist and oral sur-
898 geon.

899 To expedite post-surgical orthodontics, Insignia
900 System (Ormco Corporation, Orange, CA) is an

909 important tool for offering customized brackets and
910 archwires, alsodiminishingerrors from appliance po-
911 sitioning. Customized devices in orthodontics have
912 been reported before. Subjects treated with SureS-
913 mile (OraMetrix, Richardson, Tex) were compared
914 with those undergoing conventional orthodontic
915 treatment, concluding that treatment time was 7
916 months shorter in patients treated with SureSmile.³¹
917 Saxe³² obtained comparable results. However, SureS-
918 mile technology (OraMetrix, Richardson, Tex) cus-
919 tomizes only the archwires using robotically assisted
920 archwire bending technology.^{32,33} Insignia (Orm-
921 co Corporation, Orange County, CA) custom-
922 izes bracket prescription, bonding and archwires.¹⁴
923 Besides, the light forces produced by the passive self-
924 ligating system with high-tech archwires will control
925 the transverse dimension in coordination with post-
926 surgical sagittal changes.¹⁹

927 With 2-dimensional (2D) imaging, the most
928 usual problems are landmark identification, image
929 distortion and magnification.^{34,35} However 2D imag-
930 ing remains as the gold standard for the craniofacial
931 region. The 3D computer-assisted surgical planning
932 benefits the specialists because it can predict surgical
933 movements including translations in anteroposterior,
934 lateral, and vertical directions, and rotations around
935 the x-, y-, and z-axes, the so-called pitch, roll, and
936 yaw rotations³⁶ and this is an undisputed advantage
937 in determining the best treatment option.

938 CONCLUSIONS

939 1. The 3D diagnostics, digital surgical planning
940 and CAD/CAM customized bracket systems with
941 passive self-ligation offer a more accurate alternative
942 to improve the efficiency of orthodontic-surgical
943 treatment.

944 2. SFA helps to reduce treatment time, deliver-
945 ing aesthetic results from the beginning, which gen-
946 erates greater acceptance in surgical patients.
